Section 1 Introduction

Hydraulic modeling in the Modeling, Mapping, and Consequences (MMC) production center is based on uniform base datasets. This document describes how those base datasets are developed by the MMC Geographic Information System (GIS) mapping team for delivery to the MMC Hydraulics and Hydrology (H&H) modeling team.

The base datasets described here meet minimum criteria for use in MMC models. If higher quality data is available from the district or other source it may be used with guidance from the MMC GIS/Mapping team. All data used for MMC modeling must be compatible and comparable to the data described herein.

Listed are the primary datasets provided to H&H by the GIS/Mapping team:

Vector:

- Line of Protection (LOP)
 - Three dimensional (3D) feature class depicting the top of levee, floodwall and closure structures around a protected area. Each node on the line should have an elevation (z) value. Edited by MMC GIS/Mapping team if necessary.
- Stream Centerline
 - Digitized by MMC GIS/Mapping team
- Stream Banklines
 - $\circ \quad \text{Digitized by MMC GIS/Mapping team}$
- Levee Centerline
 - Exported from the National Levee Database (NLD) as is
- Floodwall Line
 - Exported from the NLD as is
- Closure Structure Line
 - Exported from the NLD as is
- Vertical Datum Conversion Points
 - Points along the centerline containing the conversion factor for converting elevations from National Geodetic Vertical Datum of 1929 (NGVD 29) to North American Vertical Datum of 1988 (NAVD 88) or to the official federally supported vertical datum appropriate to the geographical study area
- Leveed Area Polygon
 - o Polygon from the NLD, depicting the leveed area of the LOP

Raster:

- DEM (Digital Elevation Model) _Geo
 - Derived from the 10-meter National Elevation Dataset (NED) (latest available version at data development time) provided in native geographic projection (NAD83)
- DEM (Digital Elevation Model) _MMC
 - Derived from the 10-meter NED (latest available version at data development time) provided in MMC projection
- DEM (Digital Elevation Model) _MMC_Lev

- o Generated from the provided digital elevation model (DEM) with the LOP burned-in
- DEM (Digital Elevation Model) _MMC_Lev_R
 - Generated from the provided DEM with the LOP burned-in and resampled
- DEM (Digital Elevation Model) _MMC_Lev_R_ASC
 - ASCII file that was generated from the provided DEM with the LOP burned-in and resampled
- Hillshade
 - Generated from the provided DEM

The datasets are organized into a standard folder structure that persists throughout the life cycle of the MMC process. These files are then delivered to the assigned H&H modeler to begin hydraulic modeling using the folder structure described in Appendix 4.3.1, File Schema Guide.

Section 2 Deliverable Package Schema

All vector files will be provided in ESRI Shapefile (.shp) format. Raster data will be in ESRI Grid format. Within the naming conventions described in this document, [Proj_Code] corresponds to the three letter abbreviation for the study levee in question.

2.1 MMC PROJECTION

The projection used for modeling in the MMC is the USA_Contiguous_Albers_Equal_Area_Conic_USGS version projection with the linear units set to US feet. Each data layer below will be noted with either the MMC projection or Geographic, which corresponds to the native projection of the NED.

An ESRI .prj projection file will be provided along with the pre-modeling deliverable that can be used to project any data into the MMC projection. It is located in the *GIS_Modeling**Projections* folder.

2.2 VECTOR DATA

Layer Name	Naming Convention	Projection	
LOP	[Proj_Code]_LOP.shp	MMC	
Floodwall Line	[Proj_Code]_FL.shp	MMC	
Closure Structure Line	[Proj_Code]_CSL.shp	MMC	
Levee Centerline	[Proj_Code]_LCL.shp	MMC	
River Centerline	[Proj_Code]_CL.shp	MMC	
Banklines	[Proj_Code]_BL.shp	MMC	
Conversion Points	[Proj_Code]_Conv.shp	MMC	
Leveed Area Polygon	[Proj_Code]_LA.shp	MMC	

Table 2-1. Vector Shapefiles

2.3 RASTER DATA

Table 2-2. Raster Grids

Layer Name	Naming Convention	Projection
Native DEM	[Proj_Code]_DEM_Geo	Geographic
Model DEM	[Proj_Code]_DEM_MMC	MMC
DEM with Levee	[Proj_Code]_ MMC_Lev	MMC
Resampled DEM with Levee	[Proj_Code]_MMC_Lev_R	MMC
ASCII Grid	[Proj_Code]_MMC_Lev_R_ASC	MMC
Hillshade	[Proj_Code]_HLS	MMC

2.4 OTHER DELIVERABLE FILES

In addition to the vector and raster base data, an ArcGIS .mxd document with links to each of the datasets as well as the ESRI image services will be provided. It can be named "BaseMap.mxd" or "[Study Area] BaseMap.mxd". Also provided will be the ESRI .prj projection description file set to the MMC projection.

Section 3

Pre-Model Data Development

The following steps are designed for the GIS/Mapping team member who is assigned to develop the pre-model dataset to follow for a given levee. This document is also provided to the H&H modeler as background information to describe the development of the data that they are using. The first step to the data production process is to locate the study levee via the National Levee Database (NLD).

Once the levee location is identified and verified against aerial photography, the data production can begin. The location of the levee in the NLD should be verified using aerial photography.

3.1 FOLDER STRUCTURE

Create the deliverable folder structure shown in Figure 1 and discussed in Appendix 4.3.1 using windows explorer or ArcCatalog. Optionally, a zip file containing a blank copy of the folder structure is available from the Kansas City District (NWK) and is called MMC_File_Structure.zip.

Rename the folder called [*Study_Levee_Name*] to the three digit abbreviation of the study LOP and its NLD System ID with all spaces represented by an underscore (i.e., [*Proj_Code*]_[*FC_System_ID*]).

Rename the folder called *[Year - Draft or Final]* located directly beneath the *[Study_ Levee _Name]* folder to the fiscal year of the assignment and the word Draft separated by a single hyphen (i.e., 2012-Draft).

Create a folder under the [Year - Draft or Final] folder called Working. All processes covered in this document should use this folder as their workspace. Final data layers are moved into the appropriate folders for delivery after they are created. The Working folder is not included in the delivery to the modeler, but is archived at NWK.

If the GIS/Mapping Team member developing the data is not at NWK, the *Working* folder will be sent to NWK when the data is submitted.

3.2 PRE-MODEL GEODATABASE

All vector data generated in this process, with the exception of the levee centerline, the floodwall line, and the closure structure line, should be created directly into the MMC pre-model geodatabase schema or imported prior to export to the shapefile deliverable format. This ensures uniform data structure and provides a check on all of the datasets. Make an empty copy of the pre-model geodatabase in the *Working* folder created in step 3.1. This geodatabase is available from the GIS/Mapping Technical Lead.

The pre-model geodatabase has empty feature class templates for the eight vector datasets. The feature class schema should be fully attributed as the data is generated prior to export as a shapefile.

3.3 LINE OF PROTECTION (LOP) CREATION

The LOP is a 3D feature depicting the top of the levee, the floodwall and the closure structures that are surrounding a protected area. Each node on the line should have an elevation (z) value.

Develop the LOP:

- 1. Obtain the NLD for the district. This will be provided by NWK.
 - a. Start an edit session in ArcMap. Add the LOP feature class from the pre-model geodatabase in the *Working* folder.
 - b. From the NLD, add the levee_centerline, the closure_structure_line, the floodwall_line, and the leveed_area features for the study levee to a new ArcMap session. The first three features will be combined to depict the LOP for the study levee. The last feature will be provided to the modeler as a separate shapefile.
 - 1) Open FC_SYSTEM table and select from FC_SYSTEM table the system that is required for the model
 - 2) From the Attribute table use the Options button to select related table > FC_SEGMENT
 - 3) From the FC_SEGMENT table use Options button to select related tables
 - a) closure_structure_line, floodwall_line, levee_centerline and leveed_area
 - b) The FC_SEGMENT that was selected in the initial table will have all related segments selected in the above four tables once they are opened.
- 2. Copy and paste the selected Leveed_Area feature class into the pre-Model geodatabase Leveed_Areas feature class.
- 3. Fill in the attribute table for each leveed area:
 - a. [NLDID]—National Levee Database identification number (if applicable)
 - b. [MMCID]—Modeling, Mapping and Consequences identification number (not used)
 - c. [MMC_Name]—Name of the dam or levee project, same as used in NLD or NID
 - d. [MMC_FY]—Fiscal Year of MMC assignment
 - e. [Proj_Code]—Three letter code used in file names for pre-model data
 - f. [Del_Date]—Assigned delivery due date for pre-model data to modeler
 - g. [fc_system_id]—Primary key for the levee system in the NLD.
- 4. Export the leveed area to the *GIS_Modeling**Shapefiles* folder as a shapefile named using the three letter [Proj_Code] and LA separated by an underscore (i.e., SEG_LA.shp).
- 5. Select the closure_structure_line, floodwall_line, and levee_centerline features for the study levee.
 - a. Export the closure structures to the Working folder as a shapefile named using the three letter

[Proj_Code] and CSL separated by an underscore (i.e., SEG_CSL_NLD.shp)

- b. Export the floodwall lines to the *Working* folder as a shapefile named using the three letter [Proj_Code] and FL separated by an underscore (i.e., SEG_FL_NLD.shp)
- c. Export the levee centerlines to the *Working* folder as a shapefile named using the three letter [Proj_Code] and LCL separated by an underscore (i.e., SEG_LCL_NLD.shp)
- 6. Use the Project tool (located in the ArcGIS toolbox at *Data Management Tools–Projections and Transformations–Feature–Project*) to change the projection from the NLD projection to the MMC projection.
 - a. Save the new shapefiles to the *GIS_Modeling/Shapefiles* folder and name them [Proj_Code]_CSL.shp, [Proj_Code]_FL.shp, and [Proj_Code]_LCL.shp, respectively.
- 7. Copy and paste those three new Shapefile layers—[Proj_Code]_CSL, [Proj_Code]_FL and [Proj_Code]_LCL—into the LOP feature class in the pre-model geodatabase. Save edits.
 - a. If there is only one levee_centerline for the study levee, then the LOP is complete. If there is more than one levee_centerline, but there are no floodwall_line or closure_structure_line features for the study levee, then select all of the levee_centerline features for the study levee and merge them into one line.
 - 1) After selecting the levee_centerline feature, go to the Editor toolbar and click on the merge tool. Merge into one line.
 - b. For closure_structure_line in the LOP a determination needs to be made if the structure was collected open or closed when elevation data was collected. The expectation is that the closure was collected open, i.e., the vertices that aren't terminal will be lower than the terminal vertices which actually determine the height of the closure. If the closure was collected while open, the following edits must be made.

Note

Some closure structures will not be as described and may need special consideration.

- 1) Zoom to the location of the closures and double click the line segment that came from the closure
- 2) Press the sketch properties button

Figure 3-1. Editor toolbar

- 3) Identify the vertices with elevations lower than the first and last and delete them
- 4) Repeat process for all closure structures in the LOP, save edits, and stop editing.
- 5) Visually verify in ArcScene that the low portions of the LOP were removed
- 6) Add LOP and closure structures to view
- c. Some LOP editing may be required to close the LOP, example: if high ground exists as LOP the line may need to be closed, being mindful of capturing elevation for any added vertices.
 - 1) Utilize the Edit Sketch Properties tool on the Editor toolbar to ensure consistency in the LOP's elevation

<					>
<					

Figure 3-2. Edit Sketch Properties

d. In cases where there is a gap in the LOP due to a missing structure, or other reason, a segment should be added manually. No additional vertices are needed, but there does have to be a line there in order for it to go into Flo2D.

Figure 3-3. Example Edit Session

- 1) In an edit session, use the sketch tool to extend the line across the gap. Set snapping to "vertex" and "end" to avoid pesky under and overshoots.
- 2) With the edit select tool, double click on the arc that you snapped to, and note the Z value of the vertex you snapped to.
- 3) Press the sketch properties button as above, and locate the vertex with Z=0.00. This will be the vertex at the end of the line segment that was just digitized. Edit the Z value to be equal to the value noted in 7.d.2.
- 4) Save edits.
- 5) Visually verify in ArcScene that the low portions of the LOP were removed.
- 8. Once the LOP has been modified to depict continuity in its elevation (z) values, merge the LOP into one continuous line.
 - a. Select all of the LOP features, go to the Editor toolbar and click on the merge tool.
 - b. Merge into 1 line.
- 9. Fill in the attribute table for the LOP:
 - a. [NLDID]—National Levee Database identification number (if applicable)
 - b. [MMCID]—Modeling, Mapping and Consequences identification number (not used)
 - c. [MMC_Name]—Name of the dam or levee project, same as used in NLD or NID
 - d. [MMC_FY]—Fiscal Year of MMC assignment
 - e. [Proj_Code]—Three letter code used in file names for pre-model data
 - f. [Del_Date]—Assigned delivery due date for pre-model data to modeler
 - g. [fc_system_id]—Primary key for the levee system in the NLD

10. Export the centerline to the \GIS_Modeling\Shapefiles folder as a shapefile named using the three letter [Proj_Code] and LOP separated by an underscore (i.e., SEG_LOP.shp).

3.4 CENTERLINE CREATION

The centerline may be digitized as a shapefile and then imported into the centerlines feature class in the premodel geodatabase or digitized directly into the feature class. The centerline should be digitized so it goes past the levee extent at least three miles in each direction. If a centerline has already been created in the pre-model geodatabase, that centerline may be used; however, modify the attributes in the shapefile as necessary.

Digitize the centerline:

- 1. The most current available aerial imagery is used as the background data. If a project-specific image service is unavailable, use the ESRI world imagery service to digitize the centerline at a minimum scale of 1:15000.
- 2. The centerline must be digitized from upstream to downstream.
- 3. The centerline must be generated as a single continuous line feature.
- 4. If the centerline was digitized as a shapefile, load that feature into the centerlines feature class in the Pre-Model geodatabase, otherwise skip to step 5.
- 5. Fill in the attribute table for the centerline:
 - a. [NIDID]—National Inventory of Dams Identification number (not applicable)
 - b. [NLDID]—National Levee Database Identification number (if applicable)
 - c. [MMCID]—Modeling, Mapping and Consequences Identification number (not used)
 - d. [MMC_Name]—Name of the dam or levee project, same as used in NLD or NID
 - e. [MMC_FY]—Fiscal Year of MMC assignment
 - f. [Proj_Code]—Three letter code used in file names for pre-model data
 - g. [Del_Date]—Assigned delivery due date for pre-model data to modeler.
- 6. Export the centerline to the *GIS_Modeling**Shapefiles* folder as a shapefile named using the three letter [Proj_Code] and CL separated by an underscore (i.e., SEG_CL.shp).

3.5 BANKLINE CREATION

The banklines may be digitized as a shapefile and then imported into the banklines feature class in the premodel geodatabase or digitized directly into the feature class.

Digitize the Banklines:

- 1. The most current available aerial imagery is used as the background data. If a project specific image service is unavailable, use the ESRI world imagery service to digitize the banklines at a minimum scale of 1:15000 from the dam to the same downstream extent as the centerline.
- 2. The banklines must be digitized from upstream to downstream.

- 3. The banklines must be digitized along the right and left descending banks as separate features in the same feature class.
- 4. If the banklines were digitized as a shapefile, load those features into the banklines feature class in the pre-model geodatabase, otherwise skip to step 5.
- 5. Fill in the attribute table for each bankline:
 - a. [NIDID]—National Inventory of Dams identification number (not applicable)
 - b. [NLDID]—National Levee Database identification number (if applicable)
 - c. [MMCID]—Modeling, Mapping and Consequences identification number (not used)
 - d. [MMC_Name]—Name of the dam or levee project, same as used in NLD or NID
 - e. [MMC_FY]—Fiscal Year of MMC assignment
 - f. [Proj_Code]—Three letter code used in file names for pre-model data
 - g. [Del_Date]—Assigned delivery due date for pre-model data to modeler.
- 6. Export the banklines to the \GIS_Modeling\Shapefiles folder as a shapefile named using the three letter [Proj_Code] and BL separated by an underscore (i.e., SEG_BL.shp).

3.6 VERTICAL DATUM CONVERSION POINT CREATION

The Vertical Datum Conversion Points are generated to provide the modeler with a conversion value to use in converting existing elevation data from the NGVD 29 vertical datum to the NAVD 88 vertical datum mandated for all new modeling efforts. These conversion points are provided every five miles along the digitized centerline. Conversion values are pulled from a raster dataset of conversion values generated at a one-kilometer spatial resolution using the USACE CorpsCon conversion software. This raster dataset is available from the GIS/Mapping Technical Lead.

Prerequisites:

- Centerline shapefile must be digitized
- ESRI ArcGIS Spatial Analyst extension must be installed and enabled.

Generate Conversion Points:

- 1. Add the Conversion_Points and the centerlines feature classes from the pre-model geodatabase to an empty ArcMap document.
- 2. Start an edit session and set the editing target to the Conversion_Points feature class.
- 3. Using the feature select tool, select the centerline in the map.
- 4. Click on the Editor drop-down and choose the Divide command.
- 5. Elect to place points separated by every 26,400 units (feet) (every five miles).
- 6. Click OK. The points should be placed every five miles along the centerline.
- 7. Save edits and exit the edit session.

Extract the Conversion Raster Values:

1. Add the cf29to88 conversion value raster to the data frame. *If this layer is not available contact NWK-ED-GS

- 2. In ArcToolbox, click on Spatial Analyst Tools, choose Extraction, and then choose Extract Values to Points.
- 3. Select the Conversion Points feature class as the input point features.
- 4. Select the cf29to88 DEM as the Input raster.
- 5. Save the output shapefile to the working folder and name it "[Proj_Code]_Extract.shp"
- 6. Do not check the box to Interpolate values at point locations.
- 7. Click OK.

Populate the Attribute Table:

- 1. Join the attribute table of the newly generated point shapefile to the Conversion_Points feature class using the OBJECTID fields.
- 2. Using the field calculator, calculate the CONVDELTA field from the Conversion_Points feature class to equal the RASTERVALU from the extracted points.
- 3. Remove the Join.
- 4. Fill in the rest of the attribute table for the conversion points:
 - a. [NIDID]—National Inventory of Dams identification number (not applicable)
 - b. [NLDID]—National Levee Database identification number (if applicable)
 - c. [MMCID]—Modeling, Mapping and Consequences identification number (not used)
 - d. [MMC_Name]—Name of the dam or levee project, same as used in NLD or NID
 - e. [MMC_FY]—Fiscal Year of MMC assignment
 - f. [Proj_Code]—Three letter code used in file names for pre-model data
 - g. [Del_Date]—Assigned delivery due date for pre-model data to modeler.
- 5. Export the conversion points to the \GIS_Modeling\Shapefiles folder as a shapefile named using the three letter [Proj_Code] and Conv separated by an underscore (i.e., SEG_Conv.shp).

3.7 BUFFER CREATION FOR DIGITAL ELEVATION MODEL COMPILATION

Buffer the Leveed Area:

- 1. In a new ArcMap document add the leveed area, [Proj_Code]_LA.shp.
- 2. Use the buffer tool (Analysis Tools>Proximity>Buffer) to buffer the leveed area so that it covers the leveed area and river extents. A default buffer of three miles can be used, but review the topography to ensure that the floodplain is covered by the leveed area buffer.
 - a. Set the Dissolve Type to ALL.
 - b. Save the output as [Proj_Code]_LA_Buffer.shp in the GIS Modeling/Working folder
- 3. Verify that only one polygon has been created.

Figure 3-4. Buffer tool

Project the Leveed Area Buffer:

In order to use the buffer to set the extent of the DEM, it must be in the same projection as the DEM tiles.

- 1. Use the Project tool (located in the ArcGIS toolbox at *Data Management Tools–Projections and Transformations–Feature–Project*) to change the projection from the MMC projection to the same projection as the DEM tiles by importing the projection from one of the DEM tiles. If another elevation source is to be used, use the projection that source is provided in.
- 2. Save the new shapefile to the *Working* folder and name it [Proj_Code]_LA_Buffer_Geo.

3.8 Digital Elevation Model Compilation

Prerequisites:

- All of the DEM tiles must have a correctly defined projection.
- The map document dataframe must be set to the DEM projection.
- The Leveed Area Buffer must be in the same projection as the DEM tiles.

Find which tiles are needed:

- 1. In a new ArcMap, load the leveed area buffer shapefile that was projected to the DEM native projection in the working folder and the DEM_Extents shapefile. (Should be located with the NED data)
- 2. Click on the Selection tab on the top of the screen and choose Select by Location.
- 3. Select features from the DEM_Extents layer that intersect features in the Study Area layer.
- 4. The selected DEM tiles are the tiles that will need to be merged in the next step.

Merge the DEM Tiles (only if there is more than one DEM tile):

1. Load the DEM tiles selected in the previous step into the ArcMap document by using the attribute table of DEM Extents to locate them on disc.

Note

To prevent waiting on DEM tiles to display, it is useful to set ArcMap to not display layers as they are loaded.

- 2. Set the analysis extent of the Spatial Analyst extension to the extent of the leveed area buffer layer using the Options selection on the Spatial Analyst toolbar dropdown menu.
- 3. Using the raster calculator located in the Spatial Analyst toolbar dropdown, merge the DEMs using the following function:

"Merge([DEM1], [DEM2], [DEM3]...)"

The merge function works with the command "merge" followed by a comma separated list of raster datasets contained in parenthesis.

Note

If more than ten DEM tiles are to be merged, it is wise to do this step using about half of the tiles on the first run, then the other half, and then merging the two results together.

Convert the vertical units from meters to feet:

If the DEM tiles did not need to be merged because only one DEM tile covered the extent of the leveed area buffer, the analysis extent in the Spatial Analyst toolbar needs to be set. Go to Options and then go to the Extent tab to set the Extent Analysis to the leveed area buffer with the same projection as the DEM tiles.

Using the raster calculator again, multiply the resulting DEM (named Calculation) by 3.28084 to convert the vertical units from meters to feet.

Make the DEM permanent:

- 1. Right click on the Calculation2 (or the Calculation layer if no tiles were merged) layer resulting from the raster calculator function.
- Choose Make Permanent and store the raster in ESRI Grid format as [Proj_Code]_DEM_Geo in the \GIS_Modeling\DEMs folder. If the modeling team needs the DEM in a different projection, this is the layer they will start from.

Project the DEM:

- 1. Use the Project Raster tool (located in the ArcGIS toolbox at *Data Management Tools–Projections and Transformations–Raster–Project Raster*) to set the projection of the DEM to the MMC project projection.
- 2. Set the output raster to [Proj_Code]_DEM_MMC in the \GIS_Modeling\DEMs folder.
- 3. Set the output projection to the MMC projection.
- 4. Set the output cell size as 32.808 feet.

IMPORTANT

Set the resampling method to Bilinear instead of the Nearest Neighbor default option.

3.9 CREATE POINTS FROM LOP

Densify LOP:

- 1. A script was developed to densify the LOP vertices by inserting additional vertices to ensure that a vertice is present every ten feet. The script will output a point shapefile with Z-enabled values.
- 2. Start a new ArcMap.
- 3. Add a new toolbox.
 - a. Open ArcToolbox and right-click on it. Select New Toolbox.
 - b. A new Toolbox has been added. Rename as MMC Pre-Model Tools
- 4. Right-click on the new toolbox that was created and select Add>Script.
 - a. On the first screen set the Name and Label as DensifyLine. Click Next.
 - b. Navigate to the Python Script file. Click Next.
 - c. Set the Parameters. Click Next.
 - 1) Display Name=Input, Data Type=Shapefile, and, under Parameter Properties, Direction=Input
 - 2) Display Name=Ouput, Data Type=Shapefile, and, under Parameter Properties, Direction=Output

3) Display Name=Tolerance, Data Type=Long, and, under Parameter Properties, Direction=Input, Default=10

Figure 3-5. Add Script

- d. Click Finish.
- 5. Densify the Line every 10 feet.
 - a. Set the input to the LOP shapefile in the GIS_Modeling\Shapefiles folder
 - b. Set the output to the Working folder and name it [Proj_Code]_LOP_Points
 - c. Set the tolerance to ten feet.
 - 1) Verify that the ArcMap layer spatial reference is set to the MMC projection.

\$ Densify Line

- 6. Add XYZ coordinates to the point shapefile.
 - a. Go to Data Management>Features>Add XY Coordinates. This tool will also add Z-values.

3.10 CREATE A DISTANCE RASTER

- 1. Create a Buffer of the LOP
 - a. In a new ArcMap document, add the LOP line.
 - b. Use the buffer tool to buffer the LOP to half of the average width of the levee sloping surface as measured from aerial photography to create a polygon shapefile in the *Working* folder.

Note

If one side of the LOP is shorter than the other side, use the longer side to assure the buffer covers the entire levee.

1) Set the Dissolve Type to ALL.

À Buffer

Figure 3-16. Raster to ASCII Tool

3.16 HILLSHADE CREATION

Generate the hillshade from the projected DEM with the levee burned in:

- 1. Make sure that the Analysis Extent is set to the DEM with the MMC projection.
- 2. Choose the Hillshade tool from the Surface Analysis list under the Spatial Analyst drop-down.

- 3. Set the Input Target to [Proj_Code]_MMC_LEV
- 4. For the remainder of the inputs use the default settings to generate the hillshade dataset named [Proj_Code]_HLS in the *GIS_Modeling**DEMs* folder.

Section 4 Deliverable Organization

Organize the Data into the correct Folders:

- 1. In ArcCatalog, organize the shapefiles and rasters created in the previous steps to match the deliverable schema in Figure 1. If the files were saved into the correct folders during production they don't need moved around, only their location verified.
- 2. Ensure only the final versions of the datasets are included in the deliverable folders and leave all intermediate datasets in the working directory.

4.1 BASEMAP.MXD SETUP

An ArcMap .mxd document is provided to the modeling team to provide a first look at the data developed in the pre-model processes. The basemap can be generated from scratch or an existing basemap.mxd can be used and the data sources changed for each of the layers. The steps below describe generating the .mxd from scratch.

- 1. Open a new .mxd in ESRI ArcMap and follow the steps below to generate the document to provide to the modeling team.
- 2. Add each of the final layers to the GIS document from their final location in the folder structure.
- 3. Make sure the relative path names option is selected in the document properties, under data source options.
- 4. The layers should appear in the table of contents top to bottom in the following order:
- Conversion Points
 - Symbology: Circle, size 7, Black.
- Levee Line of Protection
 - Symbology:
 - Layer 1: Cartographic Line Symbol, Width 7, Autunite Yellow
 - Layer 2: Cartographic Line Symbol, Width 14, Steel Blue
 - Layer 3: Marker Line Symbol (Unicode 88), Size 14, Steel Blue
- Leveed Area
 - o Symbology: Outline Width 0.40

- Layer 1: Line Fill Symbol, RGB (64,101,235), Angle 45, Offset 0.003, Separation 0.0018
- Layer 2: Line Fill Symbol, RGB (151,219,242), Angle 45, Offset 0, Separation 0.0018
- Centerlines
 - Symbology: Line, Width 1, RGB (10,147,252)
- DEM (DEM with Burned-In Levee, but not Resampled)
 - Symbology: Default (turned off)
- Hillshade
 - Symbology: Default (turned off)
- ESRI Layers (ESRI Layer files provided by NWK)
 - Demographics/USA_Population_Density (turned off)
 - World Imagery (turned off)
 - o US Topo Maps (turned off)
 - World Street Map
 - Shaded Relief (turned off)
- 5. Save the .mxd into the ArcGISMaps folder as BaseMap.mxd or [Proj_Code]_BaseMap.mxd.

Section 5 Data Manifest

The Data Manifest should give a short description of the datasets that reside in each folder and of the organization responsible for the creation of the datasets. The manifest should be stored in a MS Word document in the \[Study_Levee_Name]\[Year - Draft or Final]\GIS_Modeling folder. Use the example below as a template for the structure of the manifest.

Example Manifest:

Study Area: [Study Area]

Study Area folder contains this data manifest and the production documentation describing the data development steps taken by the GIS team. Also contains all of the blank folders for use in later steps in modeling, mapping and consequence estimation.

\GIS_Modeling\ArcGISMaps

Contains the .mxd document with links to each of the datasets for this study area.

\GIS_Modeling\DEMs

Contains (list the raster datasets and any issues that might need to be addressed for any of the datasets)

\GIS_Modeling\ASCII

Contains (list the files and any issues that might need to be addressed for any of the files)

\GIS_Modeling\Projections

Contains the ESRI .prj file for the MMC projection

\GIS_Modeling\shapefiles

Contains (list the shapefiles and any issues that might need to be addressed for any of the datasets)

Data Completed By:

GIS/Mapping Team Member

District

Contact Information

Include entries for all folders that contain data. Modelers and Economists should add to this document as more data is added to the folder structure.

Section 6 Data Transfer

The data compiled and generated through the previous steps must be transferred to the H&H team to begin the modeling portion of the MMC process. One copy of the data will be sent to the modeler (all folders except for the working folder) and a full copy (including the working folder) will be saved in a central location by NWK.

- 1. Complete the checklist in Appendix 4.3.2, Pre-model Deliverable Checklist.
- 2. Use a commercial parcel delivery company (UPS, FedEx) to ship the data to the assigned H&H modeling team member as assigned.
